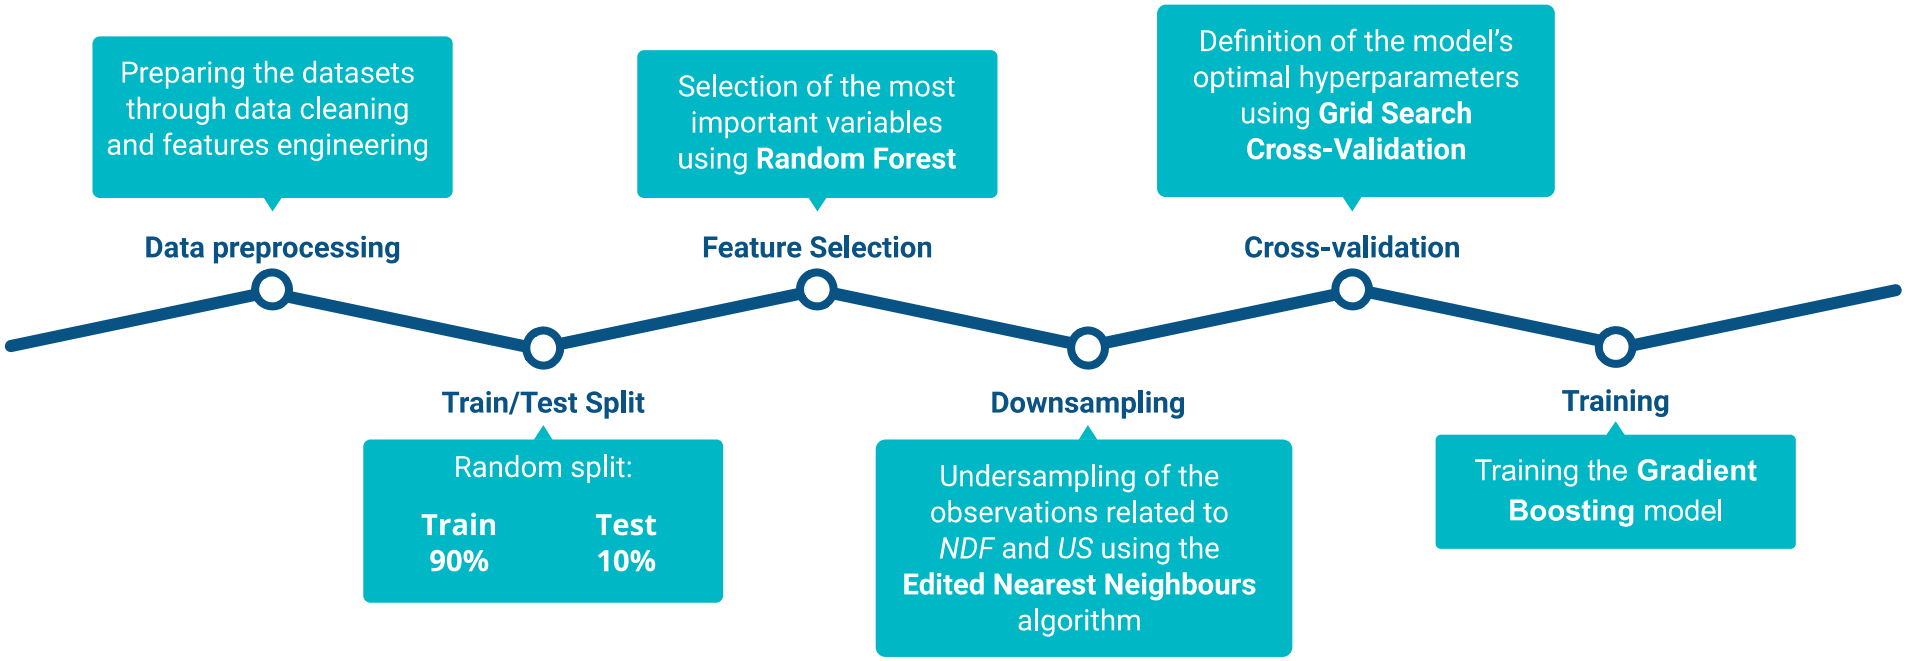
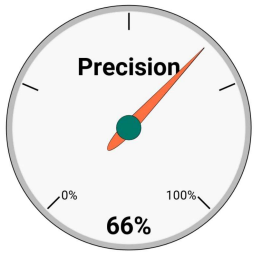
Approaching the problem



Results

Test set confusion matrix



The model is right 66 times out of 100 when it predicts an NDF

The model is able to intercept 89 TRUE NDF observations out of 100

True \ Predicted	NDF							US	other
	0	0	0	0	0	0	0	34	0	0	15	0
	0	0	0	0	1	0	0	80	0	0	44	2
	0	0	0	0	0	0	0	67	0	0	41	1

Ranking

The table contains:

User **-** user name (partially hidden)

P1_P4 **-** the first 4 predictions per user ordered for descending probability

True **-** the true destination of the user

In the sample extracted, the model gives a good ranking to the true destination of **9 users out of 10**. In all the test population, the ratio is **9.4 out of 10**.

Therefore, the model can give an accurate list of (few) probable destinations.

Conclusion

Summary

Pediction	Ranking	Recommendation
The model does not seem to be able to distinguish between the most frequent observations (*NDF*, *US* and *other*) and all the other destinations...	Anyway, when considering the **ranking** for probabilities, we observe a very accurate list of potential destinations.	If the purpose of this analysis is to guide a targeted marketing campaign, **we highly recommend focussing efforts and resources on the first 4 countries predicted per user.**

Possible improvements

It looks clear how limiting the sessions data to 6 months only of the same year affected all the training process and its results. If that limitation is due to the need of keeping the size of the files low, it may be the case to limit the extraction of the users' data to one year only but to extend that of the online sessions to the same period of time.
